BITCOIN NATIVE TOKENS · FOR BRC-100 WALLETS

Tokens that are Bitcoin

Every token is a Bitcoin output. You move it with your signature, your wallet checks it on its own, and it settles like any Bitcoin payment.

1	18 ms	~50 sat
signature moves it: yours	to trace a token back to its birth	to send one

Yours, like cash

Only your key moves it. No account, no platform, no one to ask.

Fakes never land

Your wallet traces every token it receives back to where it was born, before it shows up. When a history grows too long, a trustless checkpoint replaces the trace.

Final like Bitcoin

Every transfer is mined and proven with block headers, like any Bitcoin payment.

One format for everything

Points, tickets, coupons and one-of-a-kind collectables, in the wallet you already have.

LIVE ON MAINNET

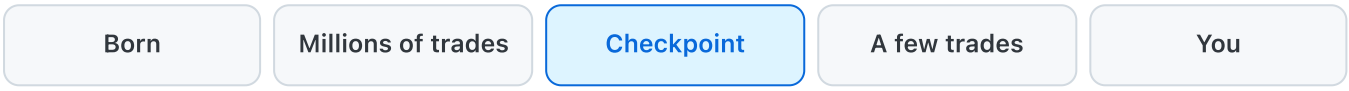

Issued, sent and merged on the public chain

WHEN A HISTORY GETS LONG

One checkpoint replaces the trace

Most tokens never need this. When a token has traded so often that tracing it gets slow, a checkpoint service proves its history once, and every wallet after that checks the checkpoint instead of the whole trace.

Short histories: your wallet

A thousand trades trace back to the start in seconds, on your device, with no service involved.

Long histories: a checkpoint service

Open servers on the overlay network prove a token's recent transfer once, so the trace stops there.

Checked, not trusted

Your wallet checks the checkpoint itself. A fake one fails. A service can only say no, and then you ask another.

Made once, passed on

The checkpoint travels with the token. Every wallet after it reuses it and passes it on.

The first checkpoints were proved from the live mainnet token on page one. Wallets check them once the checking key is published.
